Khlops

**an end-to-end solution for
Automated Machine Learning**

Nicolas Voisine

Marc Boullé

NormaSTIC 26 juin 2025

Orange needs to empower data experts (20 years ago)

1. **Business-Driven and Impact-Oriented:** Agnostic to use cases (e.g., detection of fraud, churn or anomalies), robust to poor quality data and focus on business understanding
2. **Production-Ready and Cost-Effective Scalability:** Built to process complex multi-table data structures efficiently and ensure reliable predictions in production environments
3. **Interpretability and robustness:** Ensured that models are interpretable and robust, enabling business experts to extract meaningful insights and understand the story behind the data

Focus on data and business understanding, the rest is automated

Most use cases don't justify allocating 30 guys for marginal improvements:

- Small improvements rarely influence real-world decisions and lever actions
- Over-processing just adds waste (muda) without return on investment

The green steps are for you; the rest is for the robots!

Tabular data in real-world

At school, we learn Data science with toy datasets

A statistical individual = A single row
Very easy !!

In reality, data is **much more complex**

Multi-table schema
can encode
diverse type of data

Khiops champion to handle complex data

Months of savings with Khiops

**Standard CRISP distribution
on multi-table data**

Khiops delivers results in which I always have total confidence. I save time because I question the data rather the model.

Khiops natively digest CDRs (relational data) and manages encoding and feature engineering

Distribution with Khiops

Model Interpretability for informed decision-making

Khiops results can be easily analyzed using its **built-in visualization tool**

The way each variable is linked to the target **is clear**

The final model selects only **few independant variables**

A master of frugality on big data

A single end-to-end formalism, no hyperparameters and low-level implementation for outstanding performance

- On a use case for used battery detection: Khiops was **50x faster** with **200x fewer resources** than Google AutoML
- On a benchmark based on 8 internal datasets, Khiops uses **50x fewer resources** than **Prevision.io** and **4x fewer** than **H2O** for comparable prediction performance

It's **green**, it's **cheaper**, and it adapts easily to available resources: **from mono-thread** with little memory (out-of-core) to **multi-machines** (**Kubernetes** native)

Illustration:

Khiops run on our LiveBox (very limited memory)

Calculation time for a 9Gb dataset

(500000 instances, 2000 variables, 2 classes)

More than 130 scientific publications in national and international journals and conferences

State of the art software engineering:

- **400 000** lines of code C++ for the core part
- **10 000** lines Java code for the Desktop GUI
- **15 000** lines of code for khiops-python
- **800** sets of non-regression tests
- Evaluated with volumetric test up to:
 - Hundreds of millions of instances
 - Hundreds of thousands of variables
 - Hundreds of GB for data files

Short demo

We use the « as a service » version of Khiops that would be move to open source shortly

The screenshot shows the Khiops application window. The 'Parameters' tab is selected, displaying configuration options for a Naive Bayes predictor. The 'Target variable' is set to 'Gravity' and the 'Main target value' is 'Lethal'. Under the 'Predictors' sub-tab, the 'Selective Naive Bayes predictor' checkbox is checked. The 'Feature engineering' sub-tab is also visible, showing input fields for 'Max number of constructed variables' (1,000), 'Max number of trees' (0), and 'Max number of variable pairs' (0). At the bottom, there are buttons for 'Train model' and 'Deploy model...'.

Khiops take advantage of unique formalism base on MDL*

* Minimum Description Length

MDL is used end to end !

Optimal Encoding

Formalisme MDL appliqué à la discrétisation

Étape B du pipeline : prétraitement univarié

Versicolor	34	15	1
Virginica	21	24	5
Setosa	2	18	30
Sepal width	]- inf ; 2.95[	[2.95; 3.35[	[3.35 ; inf [

Quel est le meilleur modèle ?

Formalisme MDL appliqué à la discrétisation

Une approche bayésienne de sélection de modèle

Sélection du modèle le plus probable connaissant les données:

$$\text{ArgMax } P(M|D) = \frac{\overset{\text{Prior}}{\boxed{P(M)}} \overset{\text{Likelihood}}{\boxed{P(D|M)}}}{P(D)}$$

Formalisme MDL appliqué à la discrétisation

Un critère d'optimisation régularisé

$$\mathcal{C}(M) = \log N + \log \binom{N + I - 1}{I - 1} + \sum_{i=1} \log \binom{N_i + J - 1}{J - 1} + \sum_{i=1} \log \frac{N_i!}{N_{i1}! N_{i2}! \dots N_{iJ}!}$$

Choix de la position des bornes

Choix du nombre d'intervalles

Description de la distribution des classes

Vraisemblance des données connaissant le modèle

Régularisation intrinsèque

Formalisme MDL appliqué à la discrétisation

Équilibre entre *prior* et *vraisemblance* pour lutter contre le sur-apprentissage

$$\log N + \log \binom{N + I - 1}{I - 1} + \sum_{i=1} \log \binom{N_i + J - 1}{J - 1}$$

Optimisation du « Prior » seul

A single interval

$$\sum_{i=1} \log \frac{N_i!}{N_{i1}! N_{i2}! \dots N_{iJ}!}$$

Optimisation de la « vraisemblance » seule

On interval for each « pure » zone

Formalisme MDL appliqué à la discrétisation

Le point d'équilibre dépend de la taille du jeu de données

L'exemple de la variable « Age » du dataset « Adult »

$N / 2$

N

$N \times 2$

Univariate preprocessing : optimization criterion for the discretization

The example of the crenel pattern

MODL correctly identifies the relevant information with a minimal number of instances

Variable Selection : compression gain based filtering

Why we want to select variables ?

1 – Scaling of the learning algorithms

2 – Accuracy of the learned models

Curse of dimensionality

In the literature, there are two families of variable selection approaches :

- **envelope** : The learned classifier is used to select the useful variable (ex: threshold on features importance)

- **filter** : Variables are selected before learning the classifier

Variable Selection : compression gain based filtering

What is compression gain ? (or **level** in the Khiops interface)

$$CG = 1 - \frac{-\log(P(M | D))}{-\log(P(M_0 | D))}$$

Model to be evaluated

Null model that includes a single interval / group

Ratio of coding length

- **Filtering method** : We keep only the variables with a positive compression gain
- **Intuition** : We remove variables for which the optimal model is less probable than the null model

MDL is used end to end !

Auto Features Engineering

MODL and Auto Features Engineering

A new prior with building cost

An efficient sampling algorithm for features generation

Auto Feature Engineering save time

Avoids time consuming of data-scientists

Auto Feature Engineering generate important productivity gain

Aggregates generation

Regularization:

Aggregates simpler are more probable

Aggregates are interpretable, here some examples:

1. *Mode*(Usages, Product)
2. *Max*(Usages, *YearDay*(useDate))
3. *Count*(*Selection*(Usages, *YearDay*(useDate) in [1;90] and Product="VOD"))

1 - A new prior

- Generic expression for discretization and grouping criteria:

$$c(X) = L(M_P(X)) + L(D_Y | M_P(X), D_X)$$

Coding length: *describe the model* *encode the target by using the model*

- The multi-table approach implies an additional term within the prior:

$$c(X) = L(M_C(X)) + L(M_P(X)) + L(D_Y | M_P(X), D_X)$$

construction cost

which penalizes complex aggregate features

1 - A new prior

- The new prior has a **recursive** form due to function composition ($f \circ g$)

$$L(M_C(X)) = \log(K + 1) + \log R + \sum_{op \in \mathcal{R}} L(M_C(X_{op}))$$

choice of constructing a new feature

choice of the construction rule

for each operand

Choice of constructing a new feature

- Case of original features

$$L(M_C(X)) = \log K$$

1 - A new prior

- What's appends with variable filtering ?

- Variables are filtered after the Auto Feature Engineering step (*univariate discretization and grouping*)
- Compression gains take into account the new prior for constructed variables

The filtering step favors **simple and informative** constructed variables 😊

2 – An efficient sampling algorithm

- **Objective** : draw K constructed / native variables from this prior distribution
- This prior can be represented by a tree structure
- And it consists of a **Hierarchy of Multinomial Distributions** with potentially **Infinite Depth (HMDID)**

- Major version
 - Text data
 - SNB classifier for sparse data
 - Shapley
 - Random forests for regression
 - Khiops interpretation
 - Histograms
 - Coclustering instances x variables
 - New visualization tools
 - Simplified ergonomoy

UMODL an MODL approach for Uplift

Mina Rafla, Nicolas Voisine et Bruno Cremilleux

- Uplift modeling¹ aims at estimating the change in an individual's behavior caused by a treatment.
- Y : output variable, T : treatment and X : features
Real Uplift for each individual = $Y(T = 1) - Y(T = 0)$
- Both values cannot be known simultaneously.
- So, we consider two groups: treatment and control groups.

$$CATE : \hat{r}_n = E[Y_n(T = 1)|X_n] - E[Y_n(T = 0)|X_n] \quad (1)$$

Motivation

Motivation: detect areas with homogeneous treatment effect.

- To enable us to estimate uplift for each individual
- Know feature importance

Idea: creating a discretization method that separates areas with different outcome densities in treatment and control groups.

UMODL Discretization

Proposed method: **UMODL** a method based on the MODL approach² and designed for uplift.

M : an uplift discretization model. D : data. From a Bayes point of view:

$$P(M | D) = \frac{P(M)P(D | M)}{P(D)}$$

- $P(M)$: prior
- $P(D | M)$: likelihood
- $P(D)$: constant

Objective: Maximize $P(M | D)$, hence maximize $P(M)P(D | M) \rightarrow$ Tradeoff between prior and likelihood

UMODL Discretization

We define an uplift discretization model M by the hierarchy of parameters:

- I : number of intervals
- N_i : number of instances in the interval i
- W_i : boolean term indicating if the treatment has an effect in interval i ($W_i=1$) or not ($W_i=0$)
- $\{N_{i,j}\}_{W_i=0}$: number of instances in the interval i of class j
- $\{N_{itj}\}_{W_i=1}$: number of instances in the interval i of class j and the treatment t

UMODL Discretization

By exploiting the hierarchy of parameters and assuming the independence of the local distributions for each interval:

$$P(M)P(D|M) = P(I) \times P(\{N_i\}|I) \times \prod_i P(W_i|I) [(1 - W_i) \times P(\{N_{ij}\}|I, \{N_i\}) + W_i \times \prod_t P(\{N_{it}\}|I, \{N_{it}\})] \times \prod_i P(D_i|M)$$

A discretization model is Bayes optimal if its cost is minimal. Model's cost $C(M)$:

$$\begin{aligned} C(M) = -\log(P(M)P(D|M)) &= \log N + \log \binom{N+I-1}{I-1} + I \times \log 2 \\ &+ \sum_{i=1}^I (1 - W_i) \log \binom{N_i+J-1}{J-1} + \underbrace{\sum_{i=1}^I (1 - W_i) \log \frac{N_i!}{N_{i,1}! \dots N_{i,J}!}}_{\text{Likelihood}} \\ &+ \sum_{i=1}^I W_i \sum_t \log \binom{N_{it}+J-1}{J-1} + \underbrace{\sum_{i=1}^I W_i \sum_t \log \frac{N_{it}!}{N_{it,1}! \dots N_{it,J}!}}_{\text{Likelihood}} \end{aligned}$$

UMODL Evaluation

Goal: Evaluate whether UMODL is a good uplift estimator

- 1 Define **synthetic** data patterns, for example:

UMODL Evaluation

Goal: Evaluate whether UMODL is a good uplift estimator

- 1 Define **synthetic** data patterns, for example:

$\theta = 1$

$\theta = 0.9$

$\theta = 0.8$

$\theta = 0.7$

$\theta = 0.6$

UMODL Evaluation : protocol

- 1 Define **synthetic** data patterns, for example:

- 2 Generate several datasets:
 - different sizes from 10 to 10,000 instances.
 - data is uniformly distributed on $[0, 10]$ for $T = 1$ and $T = 0$.
- 3 Generate a test set of 10K examples for the same uplift pattern.
- 4 Apply UMODL to find the Bayes optimal model.
- 5 Test the model by comparing the RMSE for each data point between:
 - the CATE estimation in the found interval and
 - the real CATE value.
- 6 Observe the number of found intervals and the RMSE, how do they behave with the data size.

UMODL Evaluation : results

- **UMODL is a good estimator of uplift:** uplift data patterns are found (i.e correct number of intervals and a RMSE close to 0.)
- **Number of instances:** when the difference of densities between intervals gets smaller, UMODL needs more data to consider a separation to two intervals.
- **UMODL does not overfit:** when the data size increases significantly, UMODL does not consider extra intervals.

Uplift Modeling Life Cycle

1. Feature selection using UMODL-FS:

```
Import kuplift as kp  
fs = kp.FeatureSelection()  
important_vars = fs.filter(df[column_names], df["treatment"], df["outcome"])
```

2. Variable transformation using UMODL:

```
Import kuplift as kp  
ue = kp.UnivariateEncoding()  
encoded_data = ue.fit_transform(df[column_names], df["treatment"], df["outcome"])
```

1. Decision trees using UB-DT:

```
tree = kp.BayesianDecisionTree()  
tree.fit(df[column_names], df["treatment"], df["outcome"])  
preds = tree.predict(df[column_names])
```

2. Random forests using UB-RF:

```
forest = kp.BayesianRandomForest(n_trees=4)  
forest.fit(df[column_names], df["treatment"], df["outcome"])  
preds = forest.predict(df[column_names])
```

KUPLIFT Package Python
